16. Abstract

This report reviews the design and performance of continuously reinforced concrete pavement (CRCP) in Illinois. Illinois has built over 4,267 two-lane km (2,650 miles) of CRCP on the Interstate system since the mid-1950s. CRCP has been constructed on nearly all urban freeways in the Chicago area and has shown excellent performance under severe weather and heavy traffic conditions. The effect of key design and construction parameters on long-term CRCP performance is investigated using a database that was compiled based on field surveys conducted from 1977 to 1994 by the Illinois Department of Transportation (IDOT). Analysis of the data shows the following variables have significant effects on performance: longitudinal reinforcement content (greatest effect of all variables), slab thickness (also very significant), traffic load applications, depth of reinforcement, base type, and D-cracking of concrete. CRCP built with tubes or chairs exhibited overall about the same performance. Experimental field studies in Illinois showed that depth of reinforcement has a large effect on crack width and, eventually, on punchouts.

ACKNOWLEDGMENTS

This report was prepared as part of the Illinois Cooperative Highway Research Program, Project 540: Enhancement to Illinois Pavement Management. The Department of Civil Engineering, University of Illinois at Urbana-Champaign, cooperated with the Illinois Department of Transportation and the United States Department of Transportation, Federal Highway Administration, to prepare this report.

DISCLAIMER

Enhancement to Illinois Pavement Management

List of IHR-540 Reports

FHWA-IL-UI-261 Performance of Original and Resurfaced Pavements on the Illinois Freeway System. Documents the survival in terms of mean age and ESALs and their distribution of both original pavements and resurfaced pavements from the 1950's to 1994.

FHWA-IL-UI-266 Work Zones and Their Impact on User Costs. Provides a brief review of the current state-of-practice concerning highway work zones (for rehabilitation activities) and their impact on user delays and costs.

FHWA-IL-UI-267 Evaluation and Improvement of the CRS Prediction Models. Evaluates two CRS prediction models and provides a new improved two-slope method that greatly improves the prediction of future CRS for a given pavement section.

FHWA-IL-UI-268 Field Performance of CRCP in Illinois. Documents the performance of many designs of CRCP on the Interstate highway system (over 2650 directional miles) constructed over the past 50 years and provides a performance prediction model that may be useful for various design and management purposes.

FHWA-IL-UI-269 Interstate 80 Pavement Rehabilitation Corridor Study. Documents the past and present, and forecasts the future performance and rehabilitation needs of the pavement sections on the Interstate I-80 highway corridor in Illinois.

TABLE OF CONTENTS

FIELD PERFORMANCE OF CONTINUOUSLY REINFORCED CONCRETE PAVEMENT IN ILLINOIS

INTRODUCTION

The majority of the pavements on the Illinois Interstate highway system (over 4,267 two-lane km [2,650 miles]) were originally constructed as continuously reinforced concrete pavements (CRCP). The first CRCP project in Illinois was constructed in 1947 on route US 40, west of Vandalia. This experimental project, still in service after 50 years, demonstrated the effect of longitudinal steel content and slab thickness on CRCP performance.

The data used in this study were collected in five field surveys conducted by IDOT in 1977, 1985, 1987, 1989, and 1994 and stored in the Illinois Pavement Feedback System (IPFS). The 1994 survey was conducted using video taping. Extensive data quality control was conducted as part of this study. The valuable results of several studies of Illinois CRCP have been used to improve the design and construction of CRCP throughout the years and are documented in the literature. *(1, 2, 3, 4, 7)*

DESCRIPTION OF ILLINOIS CRCP

The 1994 data in the Illinois Pavement Management software (ILLINET) show that there are 786 CRCP pavement management sections on the Illinois freeway system (in two directions). These sections were built between 1955 and 1994. As shown in table

1, about 96 percent of Illinois CRCP designs have ranged in thickness between 178 mm (7 in) and 254 mm (10 in). A few 153-mm (6-in) thick sections have been built, as have 279- to 330-mm (11- to 13-in) thick sections in recent projects. About 52 percent of these pavements have exhibited D-cracking, which has a very detrimental effect on performance. The 1994 pavement management data show that about 36 percent of these pavements have been overlaid. A survival analysis of these pavements conducted in 1997 showed that, on average, all CRCP designs have carried more equivalent single axle loads (ESALs) than they were designed for and have lasted longer than their design life. *(5)* The mean age and ESALs at time of overlay and design ESALs are summarized in table 2.

Table 1. CRCP thickness designs in Illinois Freeway System.

Thickness, mm (in)	Number of Sections	Length, km (mi)	Percent Length
< 178 (7)	8	93.7 (58.2)	2.2
178 (7)	84	562.2 (349.2)	13.2
203 (8)	368	2038 (1265.8)	47.8
229 (9)	182	843.9 (524.2)	19.8

279 to 330 (11 to 13)	21	64.2 (39.9)	1.5

Table 2. Survival of Illinois CRCP designs without D-cracking. (*5*)

Thickness, mm (in)	Mean Age at Time of Overlay, Years	Mean ESALs at Time of Overlay, millions	Design ESAL, millions
178 (7)	25	12	2
203 (8)	23	16	5
229 (9)	29	34	10
254 (10)	22	39	21

DATA PREPARATION AND SUMMARIZATION

The data used in this study were collected in five field surveys conducted by IDOT and stored in the IPFS database. IDOT's surveys consist of sampling 10 percent of the pavement management section within each mile. An electronic database was compiled in 1993 based on the first four surveys and additional data from the Vandalia CRCP experiment study. (*4*) The results of the fifth survey were added to the 1993 database as part of this study. The database attributes that are used in this study include the following:

- Section location: route name, direction, beginning and ending mileposts.
- Slab thickness: 178, 203, 229, or 254 mm (7, 8, 9, 10 in).
- Longitudinal steel: ranging from 0.3 to 1.0 percent of slab cross-sectional area.
- Steel placement method: chairs or tubes.
- Base type and thickness: bituminous-aggregate mixture (BAM), cement-aggregate mixture (CAM), or untreated granular base (GRAN).
- Age: ranging from 1 to 27 years.
- Cumulative ESALs: ranging from 1 to 63 million.
- Average annual Freezing Index: ranging from zero to 660 degree-days.
- Average annual temperature: ranging from 50 to 64 °F.
- Average annual precipitation: ranging from 635 to 1,016 mm (25 to 40 in).
- D-cracking: exists or does not exist.

The database contains information about 2,791.6 km (1,733.9 miles) (two directions) of Illinois CRCP divided into 476 sections and is shown in the appendix. About 40 percent of the total length of these sections exhibit D-cracking. As shown in table 3, most designs have ranged in thickness between 178 and 254 mm (7 and 10 in). Base types commonly used in Illinois CRCP are shown in table 4. Base types are mainly bituminous-aggregate mixtures, with some untreated aggregate and cement-aggregate mixtures. Occasionally, Pozzolanic aggregate mixtures and lean concrete bases are used in Illinois CRCP.

Table 3. Summary of data used in the analysis by thickness design.

Thickness, mm (in)	Number of Sections	Length, km (mi)	Percent Length
< 152 (6)	1	0.9 (0.6)	0.03
178 (7)	54	427.7 (265.7)	15.3
203 (8)	263	1591.8 (988.7)	57.0
229 (9)	123	662 (411.2)	23.7
254 (10)	32	99.7 (61.9)	3.6
279 to 330 (11 to 13)	3	9.7 (6)	0.4

Table 4. Summary of data used in the analysis by base type.

Base Type	Number of Sections	Length, km (mi)	Percent Length
BAM	407	2362.8 (1467.6)	84.6
CAM	37	300.6 (186.7)	10.8
GRAN	17	66.8 (41.5)	2.4
No Base	15	61.4 (38.1)	2.2

Table 5 shows that the vast majority of the pavements (about 94 percent) have a steel content from 0.6 to 0.65 percent or 0.7 to 0.8 percent. Eight sections with 0.3, 0.5, 0.7 and 1.0 percent steel are experimental pavements built on US 40 (west of Vandalia)

in 1947. Table 6 shows that about half of the pavements have had steel placed on chairs and the other half have had steel placed by tubes. About 90 percent of the pavements have had deformed bar reinforcement, and about 10 percent have had deformed welded wire fabric reinforcement (mesh).

Table 5. Summary of data used in the analysis by steel content.

Longitudinal Steel, percent	Number of Sections	Length, km (mi)	Percent Length
0.3 to < 0.55	5	5.8 (3.6)	0.2
0.55 to < 0.6	12	26.1 (16.2)	0.9
0.6 to < 0.65	371	2134.1 (1325.5)	76.4
0.65 to < 0.7	20	126.5 (78.6)	4.5
0.7 to 0.8	66	496.7 (308.5)	17.8
1.0	2	2.6 (1.6)	0.1

Table 6. Summary of data used in the analysis by steel type and placement method.

Reinforcement Parameter	Number of Sections	Length, km (mi)	Percent Length
Steel Type			
Bars	415	2528.7 (1570.6)	90.6
Mesh	61	262.9 (163.3)	9.4
Steel Placement Method			
Chairs	262	1402.4 (871.1)	50.2
Tubes	214	1389.2 (862.9)	49.8

The data were examined thoroughly to uncover any errors. Data examination included the following activities:

- Scatter plots.
- Each data point was assigned a code as follows:

  0, data is acceptable (trends appear reasonable)

  1, number of failures per 1.61 km (1 mile) is greater than 50

2, number of failures per 1.61 km (1 mile) is greater than 100

3, unrealistic distress history due to more than 10 percent reduction in number of failures over time, or questionable distress data.

- Review by IDOT's district and central office personnel.

Data points with a code of 2 or 3 were excluded from any further analysis. Furthermore, data points with a code 1, 2, and 3 were not used in the regression analysis. In spite of the extensive data examination, the data still showed high variation. This can be attributed to sampling only about 10 percent of the entire project and differences in survey methods. For example, the 1994 survey was conducted using video taping while previous surveys were conducted manually.

DISTRESS TYPES AND OCCURRENCE

Edge Punchouts

This distress occurs when a portion of the concrete slab of the driving (truck) lane at the free edge between two cracks punches down. Edge punchout is the primary structural distress in CRCP. It is caused primarily by repeated traffic load and loss of support. The mechanism of edge punchouts in Illinois was identified as described below. (*3*)

- Localized loss of support underneath the slab results from, repeated heavy axle loads, free moisture accumulation, disintegration of stabilized base, and pumping of stabilized or granular base.

- High deflection in the CRCP slab results in increased stress in the reinforcement and slippage between the reinforcement and concrete, that lead to widening of cracks. This leads to greater vertical shear. Also, high tensile stress in the steel can cause the fracture of surrounding concrete which, under traffic loading, results in future widening of transverse cracks. (*6*)
- Repeated traffic loads break down aggregate interlock across wide transverse cracks and causes them to rupture the steel.
- When the aggregate interlock is lost, the steel ruptures due to excessive vertical shear and corrosion.
- At this stage, the load transfer across the transverse crack is lost. Thus, the portion of the concrete slab between the two closely spaced transverse cracks acts like a cantilever beam. Traffic loads on the outer wheel path cause excessive tensile stress at the top of the slab in the transverse direction and a longitudinal crack forms between the two transverse cracks.
- Additional traffic loading causes the outside portion of the slab to depress into the base.
- The depth of the steel has a dramatic effect on crack width as subsequently noted.

D-Cracking

D-cracking is a series of many hairline cracks that become connected and allow the concrete to spall and disintegrate from freeze thaw action. It is a serious problem in Illinois, and it has affected about 50 percent of the State's CRCP. The average life of

CRCP with D-cracking is 25 percent shorter than the average life of CRCP without D-cracking. (*5*) D-cracking is caused by expansive pressure of certain types of coarse aggregates when frozen.

While the punchout is the most sever distress, other distresses that occur in CRCP include blowups at construction joints and existing transverse cracks, longitudinal cracking caused by inadequate longitudinal joint formation, and sever transverse cracking caused by longitudinal steel ruptures.

FACTORS AFFECTING CRCP PERFORMANCE

The effect of several design and construction features on the performance of CRCP is presented in this section. The investigation is based on regression analysis and summary statistics of Illinois data, field experimental sections, and data from the literature.

Regression analysis is used to investigate the effect traffic loading, slab thickness, percent steel, base type, reinforcement placement method, and D-cracking on the total number of localized failures in CRCP. The total number of failures per 1.61 km (1 mi) is computed as the sum of punchouts, existing repairs, ruptured steel transverse cracks, and localized failures (potholes). After examining several model forms and conducting a variety of analyses, the following model was found to be the best:

$$\text{Log}_e \text{FAIL} = 11.57 - 2.11 * \text{SLABTHICK}^{0.816} - 11.806 * \text{PSTEEL}^{6.53}$$
$$+ 1.643 * \log_e(\text{CESAL}) - 0.14 * \text{CAM} - 1.534 * \text{BAM}$$
$$- 0.465 * \text{GRAN} - 0.01 * \text{CHAIR} * \log_e(\text{CESAL}) + 0.397 * \text{DC}$$

where:

FAIL = Number of failures in the outer lane, # / 1.61 km (1 mi).

SLABTHICK = CRCP slab thickness, in.

PSTEEL = Longitudinal reinforcement, percent.

CESAL = Cumulative ESALs since construction, million.

BAM = 1 if base material is bituminous-aggregate mixture,
0 otherwise.

CAM = 1 if base material is cement-aggregate mixture,
0 otherwise. A limited number of lean concrete sections were included in the model development.

GRAN = 1 if base material is granular mixture,
0 otherwise.

CHAIRS = 1 if chairs used in reinforcement placement, 0 if tubes used.

DC = 1 if D-cracking exists, 0 otherwise.

Model Statistics: R^2 = 0.57

Standard Error= 4.11 failures per 1.61 km

N = 909

Figure 1 shows the correlation between predicted failures from the above model and the actual failures from the field surveys.

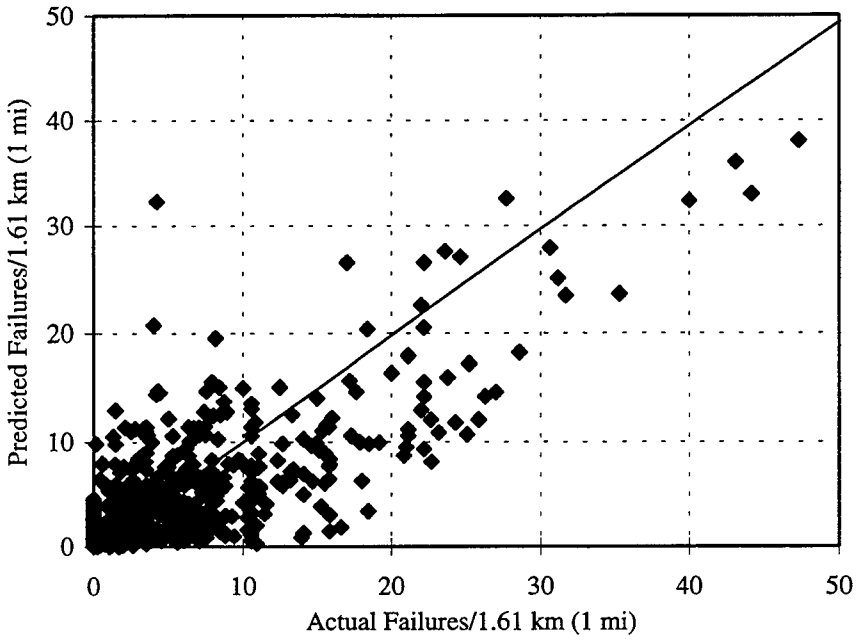

Figure 1. Actual versus predicted failures per 1.61 km (1 mi).

Percentage of Steel and Slab Thickness

Figure 2 shows the effect of slab thickness and percent steel on CRCP localized failures at 20 million ESALs using BAM base, chairs for placing steel, and no D-cracking. The worst performance occurs in thin slabs [178 mm (7 in) or less] with a low percentage of longitudinal steel (less than 0.6). Obviously, increasing thickness or percentage of steel (or both) reduces the number of failures. However, a higher longitudinal steel content has a greater effect on reducing failures in 178-mm (7-in) slabs than in 203-, 229-, or 254-mm (8-, 9-, or 10-in) slabs. Figure 3 shows the effect of slab thickness and cumulative ESALs on number of failures per 1.61 km (1 mile) in a typical project that contains steel placed on chairs, has 0.62 percent steel and BAM base, and

does not exhibit D-cracking. Increasing cumulative ESALs increases the number of failures in 178-mm (7-in) and 200-mm (8-in) slabs in a much faster rate than in thick slabs [229 mm (9 in) or 254 mm (10 in)].

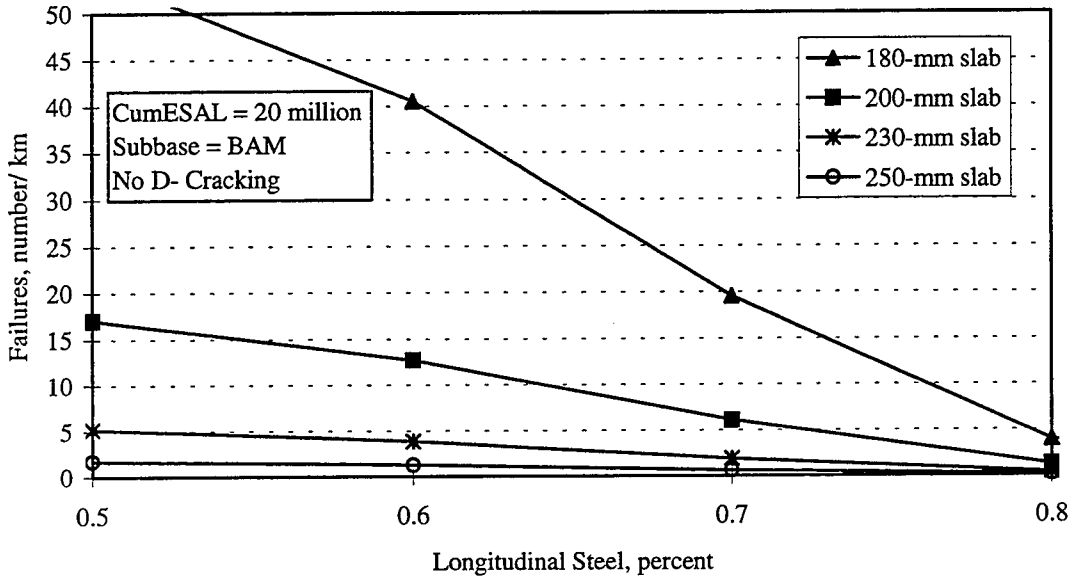

Figure 2. Effect of steel content on CRCP performance based on prediction model.

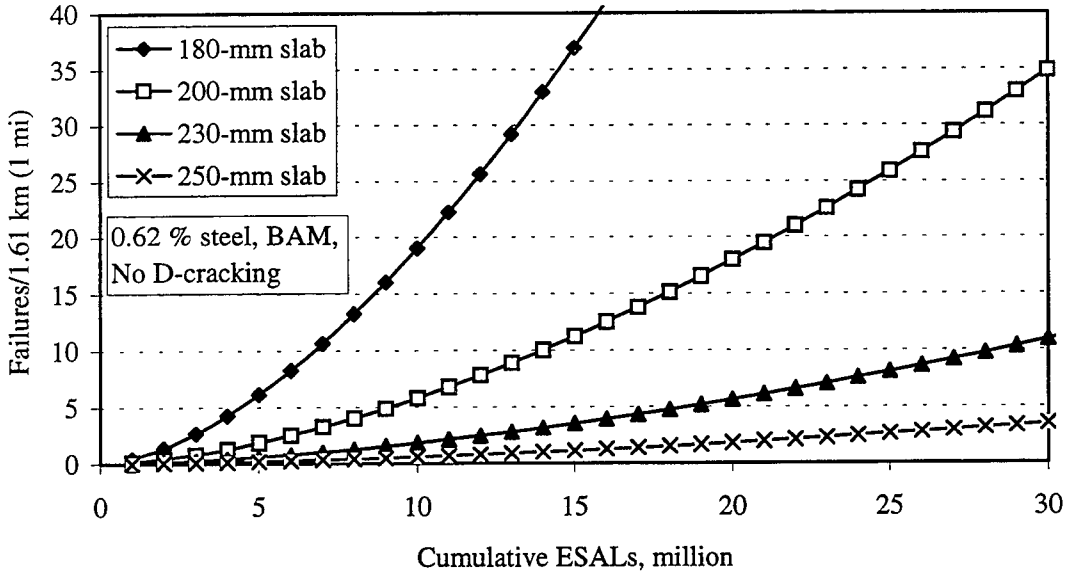

Figure 3. Effect of slab thickness on CRCP performance based on prediction model.

Table 7 summarizes the average cumulative ESALs and number of failures for Illinois sections with realistic performance history (i.e., data with a quality code = 0, 1, or 2), grouped by slab thickness and percentage of steel. For all levels of steel content, the higher the slab thickness, the lower the average number of failures per km. On average, the worst performance (19.4 failures/km [31.2 failures/mi]) occurs in the 178-mm (7-in) slabs with a low percentage of longitudinal steel. On the other hand, the best performance (no failures) occurs in the 254-mm (10-in) slabs with a high percentage of longitudinal steel (0.7 to 1 percent). However, where 178-mm (7-in) CRCP has high steel content (>0.7 to 1.0), its performance is very good even with high traffic.

Table 7. Summary of CRCP performance by slab thickness and longitudinal steel.

Longitudinal Steel, %	Category Characteristics	Slab Thickness, mm (in)			
		178 (7)	203 (8)	229 (9)	254 (10)
<0.6	Average failures/1.61 km (1 mile)	31.2	2.3	1.39	1.0
	Average ESAL, million	4.81	3.61	6.23	9.28
	No. of data points	4	5	1	16
0.6 - <0.65	Average failures/1.61 km (1 mile)	NA	4.1	3.9	2.75
	Average ESAL, million	NA	5.78	9.13	24.2
	No. of data points	0	417	320	8
0.65 - <0.7	Average failures/1.61 km (1 mile)	3.45	2.67	NA	NA
	Average ESAL, million	6.33	6.12	NA	NA
	No. of data points	8	30	0	0
0.7 – 1.01	Average failures/1.61 km (1 mile)	7.1	2.9	1.5	0
	Average ESAL, million	6.1	3.5	4.35	16.9
	No. of data points	74	6	14	20

The higher the reinforcement content the closer the crack spacing. Many of Illinois CRCP have very short crack spacing (<1 m [3 ft]) including most of the best performers. These CRCP have close crack spacing and very tight cracks and have shown excellent long-term performance under heavy traffic. After 50 years on the US40

Vandalia CRCP, the 1.0 percent steel section has a very close crack spacing (about 0.7 m [2 ft]) with no punchouts and tight cracks.

Steel Placement Method

One key purpose of this study was to compare the performance of CRCP with steel placed on chairs and CRCP with steel placed using tubes. The regression analysis shows that there is no significant difference in performance between the two steel placement methods when considering the traffic loading carried by the pavements. Figure 4 shows that there is hardly any difference in number of failures between the tubes and chairs methods for a typical CRCP project with a slab 203 mm (8 in) thick, BAM base, 0.62 percent steel, and no D-cracking. However, if chairs are used, the pavement is expected to perform slightly better at high traffic loading levels.

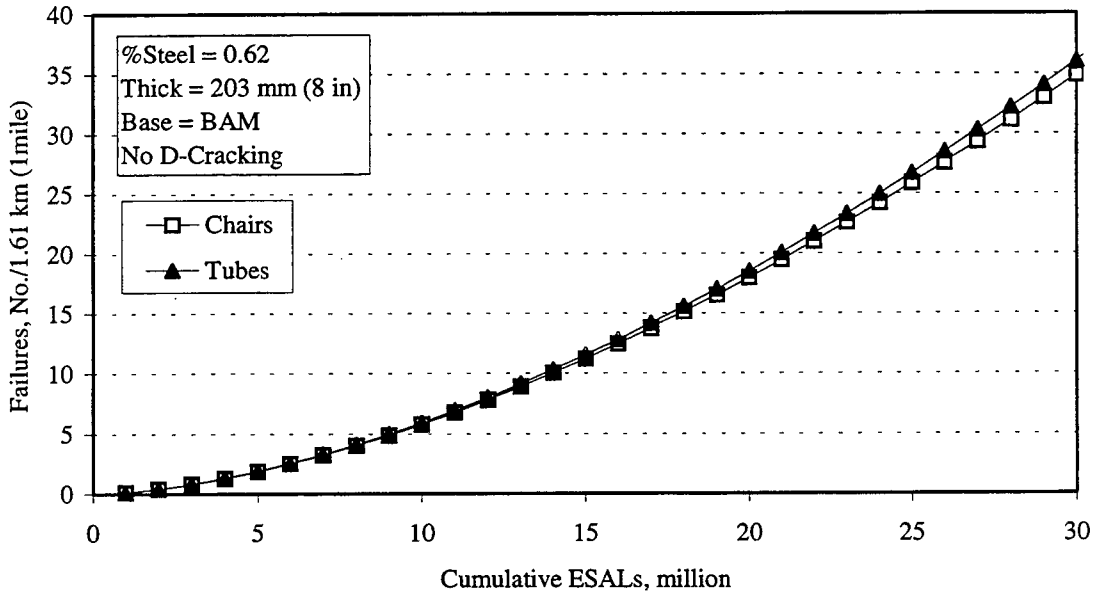

Figure 4. Effect of steel placement method on CRCP performance based on prediction model.

A survival analysis was conducted to compare the two methods based on time to overlay and ESALs carried to overlay using the LIFETEST procedure available in the PC SAS software. Figures 5 and 6 show that there is no significant difference between the two methods in terms of number of years to overlay or ESALs carried to overlay. Sections with steel placed on chairs have lasted, on average, about one year longer and carried one million ESALs more until overlay than sections with steel placed by tubes.

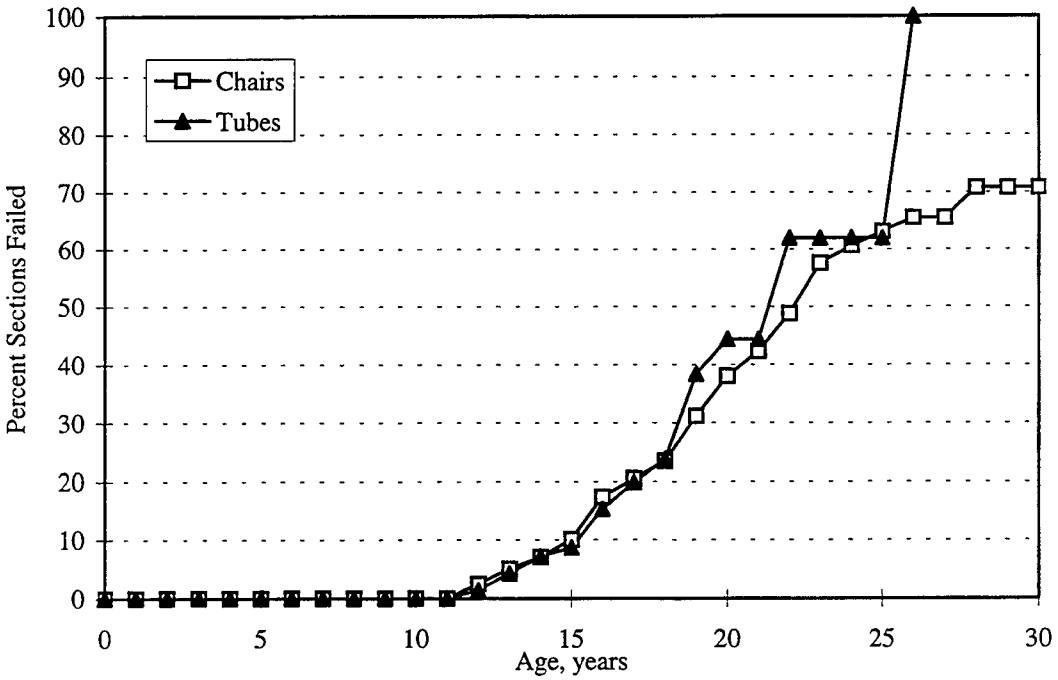

Figure 5. Age survival curve (chairs versus tubes).

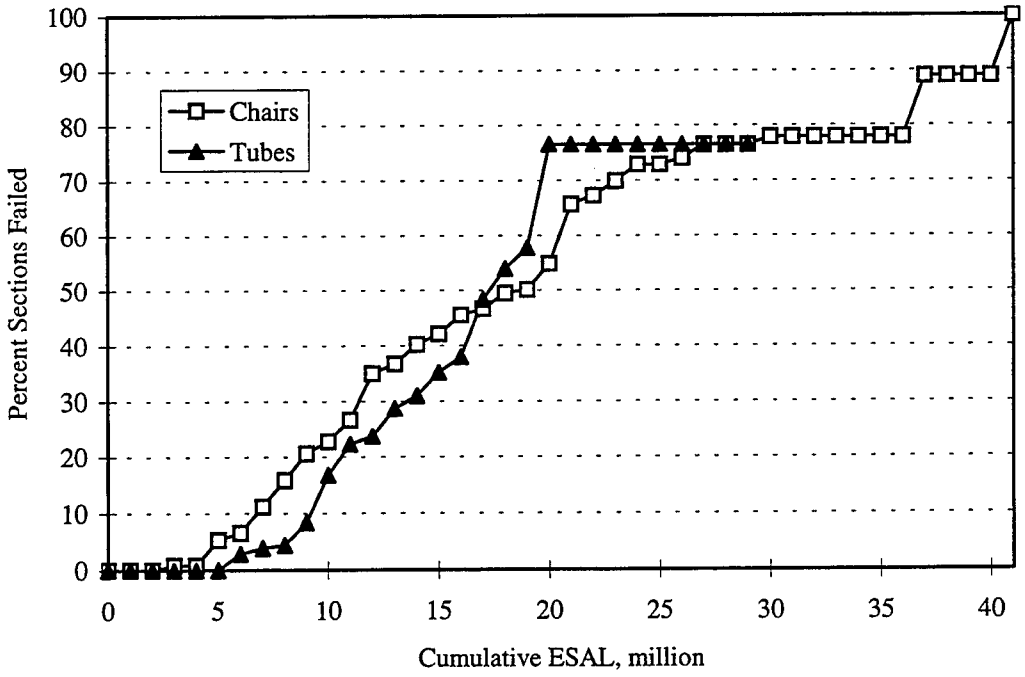

Figure 6. ESAL survival curve (chairs versus tubes).

Base Type

The regression analysis shows that sections with BAM base performed better than sections with CAM or GRAN base. Sections with GRAN base performed better than sections with CAM base. However, the strength of the CAM base may not have been adequate. As shown in table 4, there were far fewer sections with CAM or GRAN base than sections with BAM base. Sections with any of these base types performed better than sections without base and placed on the subgrade (US 40, Vandalia). This is demonstrated in figure 7 for a typical CRCP project with a slab that is 203 mm (8 in) thick, contains steel placed on chairs, has a 0.62 percent steel content, and does not exhibit D-cracking.

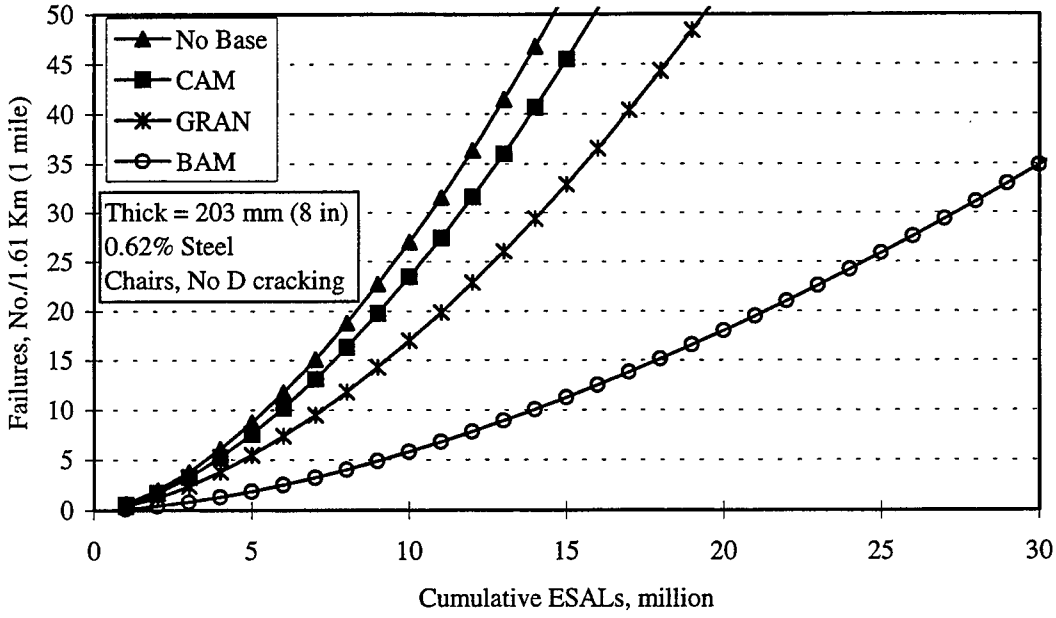

Figure 7. Effect of base type on CRCP performance based on prediction model.

Depth of Steel

Illinois has constructed an experimental project on I-70 where the depth of steel was varied from 51 to 102 mm (2 to 4 in) from the top of the 203-mm (8-in) slab. (*7*) The pavement was opened to traffic in 1963. As summarized in table 8, the results showed that the closer the steel is to the surface of the slab, the tighter the transverse cracks remain and the fewer punchouts develop over many years. At least 76 mm (3 in) of cover is needed however, for construction and to keep chlorides from reaching the steel Illinois currently places reinforcement about 89 mm (3.5 in) deep in a 254 to 305-mm (10 to 12-in) CRCP. Proper depth of steel is critical to successful performance of CRCP.

Table 8. Effect of reinforcement depth on CRCP performance, I-70 experiment. *(7)*

Reinforcement Depth, mm (in)	Crack Width in Winter, mm (in) (pavement age = 9 years)	Patching, $ft^2/1000\ ft^2$ ($m^2/1000\ m^2$) (pavement age = 14 years)
51 (2)	0.475 (0.0187)	7.0 (7.0)
76 (3)	0.7925 (0.0312)	12.7 (12.7)
102 (4)	0.8306 (0.0327)	30.9 (30.9)

Based on a previous investigation, a crack width of 0.51 mm (0.02 in) is required. *(8)* Thus, 0.51 mm (0.02 in) is recommended as the design crack width to protect against spalling and water penetration.

Other factors that may affect the performance of CRCP include epoxy coated steel bars and pavement stiffness. Unfortunately, there is not enough data to discover any performance differences between CRCP with epoxy-coated steel and CRCP with plain steel. However, if the epoxy reduces the bond between the concrete and reinforcement, the cracks may widen and eventually lead to punchouts. Previous research efforts indicated that the slab rigidity (D) characterizes the effective pavement stiffness along the edge better than the radius of relative stiffness (l). (9) It is recommended that the deflection data on Illinois CRCP be used to backcalculate D and that potential relationships between D-value and the cracking pattern be investigated.

SUMMARY AND CONCLUSIONS

This report reviews the design and performance of CRCP in Illinois. Analysis of over 2791.6 km (1733.9 miles) (two directions) of Illinois CRCP divided into 476 pavement management sections indicated the following:

- CRCP of all thickness designs and steel content have carried more ESALs and have lasted 2 to 6 times longer than they were designed.
- CRCP sections with a slab 178 mm (7 in) thick and a steel content less than 0.6 percent have the most failures among all sections under study.
- CRCP sections with a slab 254 mm (10 in) thick and a steel content from 0.7 to 0.8 percent have the lowest failures among all sections under study.
- A higher longitudinal steel content has a greater effect on reducing failures in 178-mm (7-in) slabs than in 203-, 229-, or 254-mm (8-, 9-, or 10-in) slabs.
- Field results clearly show that crack tightness is critical, whereas, crack spacing can be very short (<1 m [3 ft]). Increased steel content keeps tight cracks and short crack spacing.
- No significant difference occurred between the performance of CRCP with steel placed on chairs and steel placed using tubes.
- Sections with bituminous-aggregate mixture base performed better than sections with cement-aggregate mixture base or granular base. Sections with any of these base types performed better than sections without base.
- The closer the steel is to the surface of the slab, the tighter the transverse cracks remain and the fewer punchouts develop over many years. At least 76

mm (3 in) of cover is needed however, for construction and to keep chlorides from reaching the steel.

%Steel	Percent longitudinal steel
Age	Pavement age, years
CESAL	Cumulative ESALs, million
M&HSevDC	Y if medium or high-severity D-cracking exists, N otherwise
DistressYr	Distress survey year
Fail/Mile	Number of failures per mile in the outer lane
District	IDOT district
ClimZone	Climatic zone
FI	Freezing Index, degree-days
Temp	Average annual temperature, °F
Prec	Average Annual precipitation, in
CrkSps	Crack spacing, ft
Code	3 if distress history (number of failures/mile) is questionable
	2 if number of failures/mile > 100 and distress history is not questionable
	1 if number of failures/mile > 50 and distress history is not questionable
	0 otherwise
NA	Not Available
